

Abstract

- There are system defined objects, which are predefined and come with the JavaScript parser or with the browser running the parser.
- And there are user defined objects, which the programmer creates.
- There are two important concepts to understand when talking about objects.

- First you must define a class of objects, then you use the object class by declaring instances of that class within the program.
- The object class is a definition, or description, of how the object is supposed to be created, what it contains, and how it works.
- The object instance is a composite data type, or object, created based on the rules set forth in the class definition.
